The Kinematics of Deep Inelastic Scattering in the Presence of Initial State Radiation

Günter Wolf

Deutsches Elektronen Synchrotron DESY

Abstract

Initial state radiation (ISR) in deep inelastic scattering of charged leptons on nucleons can lead to substantial shifts in the reconstruction of Q^2 and the scaling variables x and y . By measuring at least three out of the four variables: energy and production angle of the lepton and the hadron system, the energy of the ISR photon emitted under zero degrees can be determined. The ISR effect is illustrated for experimentation at HERA with different methods of kinematic reconstruction.

1 Introduction

The kinematics of deep-inelastic electron proton scattering (DIS) by neutral current exchange (NC),

$$ep \rightarrow eX, \tag{1}$$

is characterized by the mass squared ($-Q^2$) of the exchanged current and the Bjorken scaling variable x . In a hermetic detector, Q^2 and x can be determined from the

energy and angle of the scattered electron or from the energy and momentum components of the produced hadron system or from a combination of any other two of these quantities [1, 2, 3].

The determination of x and Q^2 is erroneous when the incoming electron radiates a photon before the hard interaction takes place (initial state radiation, ISR)¹. When averaged over a large DIS event sample, the effect of ISR in general is rather small². However, ISR can have an important effect when, due to ISR, events produced in a $Q^2 - x$ region of large cross section migrate into a region where the cross section is expected to be small. An example for such a constellation is presented by the possible excess of high- x , high- Q^2 events recently observed at HERA [5, 6].

Most of the ISR photons are emitted very close to the direction of the electron such that the emission angle can be assumed to be zero (peaking approximation). The ISR energy and the Q^2, x values can then be obtained on an event-by-event basis from a measurement of three out of the four quantities mentioned above [1, 2, 3, 4] or from a global fit [7].

In charged current (CC) processes,

$$ep \rightarrow \nu X, \quad (2)$$

where the ν escapes detection the information from the hadron system can be used to put a limit on the energy emitted by ISR while a measurement requires direct observation of the ISR photon.

This note presents the relevant formulae in a form suitable for HERA experiments and illustrates the migration of events due to ISR in the $x - y$, $x - Q^2$, $y - Q^2$ and $M - y$ planes, where M is the effective mass of the electron current quark system.

2 DIS kinematics in the absence of ISR

In deep-inelastic ep scattering (eq. 1) depicted in Fig. 1 the incoming electron couples to the neutral electroweak current $J = \gamma, Z^0$. The relevant variables in the *absence* of QED radiative effects are:

¹Due to the comparatively large mass of the proton, ISR from the incoming proton can be neglected. In principle, photon emission by the scattered electron (final state radiation, FSR) will affect also the determination of the kinematics; in practice, if the scattered electron is detected in a calorimeter, the effect will be small because the signals from the electron and the FSR photon are summed.

²For DIS at HERA with Q^2 between 10 and 100 GeV², roughly 6% of the events have an ISR photon carrying between 5 and 20% of the energy of the incident electron.

E_p	proton beam energy
E_e	electron beam energy
$p = (0, 0, E_p, E_p)$	four momentum of incoming proton with mass m_p
$e = (0, 0, -E_e, E_e)$	four momentum of incoming electron
$e' = (E'_e \sin \theta'_e, 0, E'_e \cos \theta'_e, E'_e)$	four momentum of scattered electron
$s = (e + p)^2 = 4E_p E_e$	square of total ep c.m. energy
$q^2 = (e - e')^2 = -Q^2$	mass squared of exchanged current J = square of four momentum transfer
$\nu = q \cdot p / m_p$	energy transfer by J in p rest system
$\nu_{max} = s / (2m_p)$	maximum energy transfer
$y = (q \cdot p) / (e \cdot p) = \nu / \nu_{max}$	fraction of energy transfer
$x = Q^2 / (2q \cdot p) = Q^2 / (ys)$	Bjorken scaling variable
$q_c = x \cdot p + (e - e')$	four momentum of current quark
$M^2 = (e' + q_c)^2 = x \cdot s$	mass squared of electron - current quark system.

The electron and proton masses (m_e, m_p) have been neglected. The angle θ'_e of the scattered electron is measured with respect to the incoming proton (see Fig. 1b). For simplicity, the scattered electron has been assumed to have zero azimuthal angle. For fixed c.m. energy $\sqrt{s}$, the inclusive process $ep \rightarrow eX$ is described by two Lorentz-invariant variables which can be determined from the electron or the hadronic system.

The electron side yields:

$$\begin{aligned}
y &= 1 - \frac{E'_e}{2E_e}(1 - \cos \theta'_e) \\
Q^2 &= 2E_e E'_e(1 + \cos \theta'_e) \\
x &= E'_e(1 + \cos \theta'_e) / (2yE_p) \\
E'_e &= (1 - y)E_e + xyE_p \\
\cos \theta'_e &= \frac{xyE_p - (1 - y)E_e}{xyE_p + (1 - y)E_e} \\
E_e'^2 \sin^2 \theta'_e &= 4xy(1 - y)E_e E_p.
\end{aligned} \tag{3}$$

With the help of the relation $M = \sqrt{x \cdot s}$ the variable x can be replaced by the mass M of the electron current quark system.

Neglecting the proton remnant, the hadron system j , with energy E_j and production angle θ_j , yields:

$$\begin{aligned}
y &= \frac{E_j}{2E_e}(1 - \cos \theta_j) \\
Q^2 &= E_j^2 \sin^2 \theta_j / (1 - y)
\end{aligned}$$

$$\begin{aligned}
x &= \frac{E_j}{2E_p}(1 + \cos\theta_j)/(1 - y) \\
E_j &= yE_e + x(1 - y)E_p \\
\cos\theta_j &= \frac{-yE_e + (1 - y)xE_p}{yE_e + (1 - y)xE_p} \\
E_j^2 \sin^2\theta_j &= 4xy(1 - y)E_e E_p = Q^2(1 - y).
\end{aligned} \tag{4}$$

Using the method of Jacquet-Blondel [8] the hadron variables can be determined approximately by summing the energies (E_h) and transverse (p_{Th}) and longitudinal momenta (p_{Zh}) of all final state particles. The method rests on the assumption that the total transverse momentum carried by those hadrons which escape detection through the beam hole in the proton direction as well as the energy carried by particles escaping through the beam hole in the electron direction can be neglected. The result is:

$$\begin{aligned}
y_{JB} &= \frac{1}{2E_e} \sum_h (E_h - p_{Zh}) \\
Q_{JB}^2 &= \frac{(\sum_h p_{Xh})^2 + (\sum_h p_{Yh})^2}{1 - y_{JB}} \\
x_{JB} &= Q_{JB}^2 / (y_{JB} s)
\end{aligned} \tag{5}$$

The double-angle (DA) method of [1] uses the electron scattering angle and the angle γ_h which characterizes the longitudinal and transverse momentum flow of the hadronic system (in the naive quark-parton model γ_h is the scattering angle of the struck quark):

$$\cos\gamma_h = \frac{(\sum_h p_{Xh})^2 + (\sum_h p_{Yh})^2 - (\sum_h (E_h - p_{Zh}))^2}{(\sum_h p_{Xh})^2 + (\sum_h p_{Yh})^2 + (\sum_h (E_h - p_{Zh}))^2} \tag{6}$$

leading to

$$\begin{aligned}
Q_{DA}^2 &= \frac{4E_e^2 \sin\gamma_h (1 + \cos\theta'_e)}{\sin\gamma_h + \sin\theta'_e - \sin(\gamma_h + \theta'_e)} \\
x_{DA} &= \frac{E_e}{E_p} \cdot \frac{\sin\gamma_h + \sin\theta'_e + \sin(\gamma_h + \theta'_e)}{\sin\gamma_h + \sin\theta'_e - \sin(\gamma_h + \theta'_e)} \\
y_{DA} &= \frac{\sin\gamma_h (1 + \cos\theta'_e)}{\sin\gamma_h + \sin\theta'_e + \sin(\gamma_h + \theta'_e)} \\
&= \frac{(1 - \cos\gamma_h) \sin\theta'_e}{\sin\gamma_h + \sin\theta'_e - \sin(\gamma_h + \theta'_e)} \\
&= Q_{DA}^2 / (x_{DA} s).
\end{aligned} \tag{7}$$

The energy of the scattered electron obtained by the DA-method is:

$$E'_{eDA} = 2 E_e \frac{\sin \gamma_h}{\sin \gamma_h + \sin \theta'_e - \sin(\gamma_h + \theta'_e)}. \quad (8)$$

The Σ method [3] combines the measurements of the energies and angles of the electron and hadron system. Making use of the relation

$$\sum_h (E_h - p_{Zh}) + E'_e (1 - \cos \theta'_e) = 2E_e, \quad (9)$$

which holds exactly for a hermetic detector, one can write

$$\begin{aligned} y_\Sigma &= \frac{\sum_h (E_h - p_{Zh})}{\sum_h (E_h - p_{Zh}) + E'_e (1 - \cos \theta'_e)} \\ Q_\Sigma^2 &= \frac{E'_e \sin^2 \theta'_e}{1 - y_\Sigma} \\ x_\Sigma &= \frac{Q_\Sigma^2}{s y_\Sigma}. \end{aligned} \quad (10)$$

3 DIS kinematics with ISR

The photon from ISR is assumed to be emitted in the direction of the beam electron (see Fig. 2). In order to avoid confusion, the kinematic quantities of the beam particles will be denoted by the subscript *beam*; those of the particles participating in the hard interaction will be denoted by the subscript *true*. The “measured” variables are those obtained under the assumption of no ISR emission. They will be identified by the method of reconstruction (i.e. e, DA or JB method) and by the subscript *meas*. They will be assumed to be measured without errors. For ease of reference all relevant variables are listed below:

Initial state (nominal):

E_{pbeam}, E_{ebeam}	proton and electron beam energies
$s_{nominal} = 4E_{pbeam} E_{ebeam}$	square of nominal ep c.m. energy

ISR photon:

E_γ	energy of the ISR photon
$f_\gamma = E_\gamma / E_{ebeam}$	fraction of electron beam energy carried by ISR
$E_{ettrue} = (1 - f_\gamma) E_{ebeam}$	energy of incoming electron in the hard interaction

Hard interaction:

$x_{true}, y_{true}, Q_{true}^2$	true values
$x_{emeas}, y_{emeas}, Q_{emeas}^2$	x, y, Q^2 obtained with the e-method
$E'_{e\,emeas}, \theta'_{e\,emeas}$	E'_e, θ'_e obtained with the e-method
$x_{DAmeas}, y_{DAmeas}, Q_{DAmeas}^2$	x, y, Q^2 obtained with the DA method
$E'_{e\,DAmeas}$	E'_e obtained with the DA-method
$x_{JBmeas}, y_{JBmeas}, Q_{JBmeas}^2$	x, y, Q^2 obtained with the JB method
$x_{\Sigma}, y_{\Sigma}, Q_{\Sigma}^2$	x, y, Q^2 obtained with the Σ method

The effect of ISR is taken into account by replacing in eqs. 3 to 7 the electron beam energy by E_{true} . The result is

$$s_{true} = (1 - f_{\gamma})s_{nominal} \quad (11)$$

and for the electron method:

$$\begin{aligned}
x_{true} &= x_{emeas} \frac{y_{emeas}}{y_{true}} \\
&= x_{emeas} \frac{y_{emeas}(1 - f_{\gamma})}{y_{emeas} - f_{\gamma}} \\
y_{true} &= \frac{y_{emeas} - f_{\gamma}}{1 - f_{\gamma}} \\
Q_{true}^2 &= Q_{emeas}^2 (1 - f_{\gamma}).
\end{aligned} \quad (12)$$

One finds for the electron method that

- f_{γ} cannot exceed y_{emeas} : $f_{\gamma} < y_{emeas}$. f_{γ} is limited also by the condition $x_{true} \leq 1$ which leads to $f_{\gamma} \leq \frac{y_{emeas}(1-x_{emeas})}{1-x_{emeas}y_{emeas}}$;
- all three variables (x, y, Q^2) are affected by ISR. In the presence of ISR the points move in the x, y plane along lines of constant Q_{emeas}^2 : note, $x_{emeas}y_{emeas} = x_{true}y_{true}$ and therefore $Q_{emeas}^2 = s_{nominal}x_{emeas}y_{emeas} = s_{nominal}x_{true}y_{true}$. Since ISR reduces s the true Q^2 value is smaller than Q_{emeas}^2 .
- the measured x value is smaller than the true one, $x_{emeas} < x_{true}$;
- the measured y value is larger than the true one, $y_{emeas} > y_{true}$. At small y the shift in y - and therefore also in x - can become quite large, e.g. for $f_{\gamma} = 0.1$, $y_{true} = 0.2$ one finds $y_{emeas} = 1.4y_{true}$ and $x_{emeas} = 0.7x_{true}$.

The corresponding results for the DA variables are:

$$\begin{aligned}x_{true} &= (1 - f_\gamma) \cdot x_{DAmeas} \\y_{true} &= y_{DAmeas} \\Q_{true}^2 &= Q_{DAmeas}^2 \cdot (1 - f_\gamma)^2.\end{aligned}\tag{13}$$

One finds for the DA method that

- x and Q^2 are affected by ISR while y is insensitive to ISR;
- the measured x value is larger than the true one, $x_{DAmeas} > x_{true}$;
- ISR has a strong effect on Q^2 since the factor $(1 - f_\gamma)$ enters quadratically. To give an example, for $f_\gamma = 0.2$ and $Q_{true}^2 = 20000 \text{ GeV}^2$, the measured Q^2 value is more than 50% larger, viz. $Q_{DAmeas}^2 = 31250 \text{ GeV}^2$.

The results for the Jacquet-Blondel method are:

$$\begin{aligned}x_{true} &= x_{JBmeas} \frac{1 - y_{JBmeas}}{1 - y_{JBmeas}/(1 - f_\gamma)} \\y_{true} &= y_{JBmeas} \frac{1}{1 - f_\gamma} \\Q_{true}^2 &= Q_{JBmeas}^2 \frac{1 - y_{JBmeas}}{1 - y_{JBmeas}/(1 - f_\gamma)}\end{aligned}\tag{14}$$

One finds for the JB method that

- f_γ cannot exceed $(1 - y_{JBmeas})$: $f_\gamma < (1 - y_{JBmeas})$. f_γ is limited also by the condition $x_{true} \leq 1$ which leads to $f_\gamma \leq \frac{(1 - x_{JBmeas})(1 - y_{JBmeas})}{1 - x_{JBmeas}(1 - y_{JBmeas})}$;
- x, y and Q^2 are affected by ISR.

The results for the Σ method are:

$$\begin{aligned}x_{true} &= \frac{x_{\Sigma meas}}{1 - f_\gamma} \\y_{true} &= y_\Sigma \\Q_{true}^2 &= Q_\Sigma^2.\end{aligned}\tag{15}$$

One finds for the Σ method that

- y and Q^2 are not affected by ISR. This is so because eq. 9 holds also in the presence of ISR when E_{true} is used for E_e instead of E_{beam} .
- Note that M is also unaffected by ISR since $M^2 = x_{true}s_{true} = x_{\Sigma meas}s_{nominal}$.

3.1 Graphical illustration of ISR effects

The effects of ISR on the measurements of x, y and Q^2 when using the e, DA, JB and Σ methods have been calculated for collisions of $E_{ebeam} = 27.5$ GeV electrons on $E_{pbeam} = 820$ GeV protons. The results for the $x - y$, $x - Q^2$, $y - Q^2$ and $M - y$ planes are presented in Figs. 3 to 16 for two values of the fractional energy carried away by the radiated photon: $f_\gamma = 0.1$ and 0.2 . The arrows shown point from the measured to the true quantities. The curves in the $x - y$ and $M - y$ diagrams show lines with constant Q_{meas}^2 .

3.2 Determination of the energy of the ISR photon

In selecting DIS events the HERA experiments H1 and ZEUS place a cut on the difference between the total energy and longitudinal momentum

$$\delta = \sum(E - pz) \quad (16)$$

observed in the detector which puts a limit on the energy of possible ISR. For a hermetic detector $\delta = 2E_{ebeam}$. If the ISR photon escapes detection the requirement $\delta \geq \delta_{min}$ limits the photon energy:

$$E_\gamma = E_{ebeam} - \delta/2 < E_{ebeam} - \delta_{min}/2 \quad (17)$$

and therefore

$$f_\gamma < 1 - \delta_{min}/(2E_{beam}), \quad (18)$$

provided that measurement errors and other detector effects can be neglected.

ISR in general affects the variables x, y, Q^2 differently when measured with the electron, DA or JB methods. For instance, in the presence of ISR the x value measured with the electron method is always smaller than the true value, x_{true} , while the x value obtained with the DA method is always larger than x_{true} . Turning the argument around, if one observes $x_{emeas} < x_{DAmeas}$ and $Q_{emeas}^2 < Q_{DAmeas}^2$ then this is a strong indication for the emission of ISR, provided measurement errors can be neglected.

The energy carried by the ISR photon can be determined directly from a comparison of the variables found with the different methods. Assuming that measurement errors can be neglected one obtains

from the comparison of e and DA variables:

$$\begin{aligned}
f_\gamma &= 1 - \frac{E'_{e\,meas}}{E'_{DAmeas}} \\
&= y_{e\,meas} \left(1 - \frac{x_{e\,meas}}{x_{DAmeas}}\right) \\
&= \frac{y_{e\,meas} - y_{DAmeas}}{1 - y_{DAmeas}} \\
&= 1 - \frac{Q_{e\,meas}^2}{Q_{DAmeas}^2},
\end{aligned} \tag{19}$$

from the comparison of e and JB variables:

$$\begin{aligned}
f_\gamma &= y_{e\,meas} - y_{JBmeas} \\
&= (1 - y_{JBmeas}) \left(1 - \frac{Q_{JBmeas}^2}{Q_{e\,meas}^2}\right)
\end{aligned} \tag{20}$$

and from the comparison of DA and JB variables:

$$\begin{aligned}
f_\gamma &= 1 - \frac{y_{JBmeas}}{y_{DAmeas}} \\
&= (1 - y_{JBmeas}) \left(1 - \frac{x_{JBmeas}}{x_{DAmeas}}\right)
\end{aligned} \tag{21}$$

In the Σ method the result is

$$f_\gamma = 1 - \frac{\Sigma_h(E_h - p_{Zh}) + E'_e(1 - \cos\theta'_e)}{2E_{beam}}. \tag{22}$$

Of course, the most precise result for NC processes on f_γ can be expected from a common fit to all variables measured as advocated in [7].

As mentioned before, for CC processes, the ISR energy must be determined from the direct observation of the photon. The information from the hadron side allows only to put a limit on the photon energy: $f_\gamma < (1 - y_{JBmeas})$.
